

USE CASES

FIND YOUR SITUATION

The same architecture serves a wellhead, a bottling line, a pump station. Almost nobody buys everything on day one. Most plants buy one product for one problem, then add the next one when it shows up.

ROUTING

START HERE

Find the row that sounds like your plant. The last column is what fixes it and what it costs: list price, per gateway, bought once and kept.

IF THIS IS YOUR SITUATION	WHAT CHANGES FOR THE BUSINESS	WHAT YOU BUY
A remote site on cellular or satellite. The link drops, and the data bill keeps climbing.	The site reports changes instead of restating the same reading, keeps everything on disk while the link is down, and gives you a plain list of what is actually spending the budget.	SparkBridge Edge \$995, with SparkLink included free. Standalone; nothing else installs at the site.

[● ASK AN ENGINEER](#)

IF THIS IS YOUR SITUATION	WHAT CHANGES FOR THE BUSINESS	WHAT YOU BUY
Forty sites landing on one central server that is already stretched thin and cannot ride out a network outage.	Each site holds its own data during an outage and reports only what changed. The central server stops working harder every time someone adds a new dashboard.	SparkBridge Host \$1,495 once, plus SparkBridge Edge \$995 per site. See the products
A trend that runs flat through an outage and then jumps. Nobody can defend the report built on it.	Every reading keeps the time it actually happened. A backlog lands where it belongs, and the trend shows what the plant really did.	SparkVault \$3,995. Host gateway only.
Analysts reconciling duplicate rows in the warehouse by hand, and never quite trusting the totals.	Every reading lands exactly once in your own warehouse. A restart or a dropped connection can no longer leave a gap or a duplicate.	SparkInject \$2,995. Host gateway, per connector family.
A historian or SCADA package that will never be replaced, and still needs the same live data.	Your existing tools connect the way they already do. No custom connectors, no integration project.	Passage \$1,995. Read only. It cannot write or command.
The same efficiency number, hand built in a PLC, a dashboard and a spreadsheet, giving three different answers.	The number is calculated once, in one place, then used everywhere. Everyone in the building looks at the same figure.	SparkCalc Included with Host. Runs at a site or centrally.
Nobody can say what the plant network is exposing, and an auditor is asking for evidence.	A scored report of what is wrong, ranked by risk, with the evidence behind each finding and the fix for it. It	Sentinel \$4,995. Compliance pack \$2,495.

IF THIS IS YOUR SITUATION	WHAT CHANGES FOR THE BUSINESS	WHAT YOU BUY
	only observes and changes nothing.	
One compromised site could write another site's data, or send a command to equipment it has no business touching.	A read permission never quietly includes the ability to control equipment. Access is scoped to one site on purpose.	<u>SparkID</u> Included with Host. Host gateway.
Forty gateways in the field and nobody knows which version, which drifted, or which certificate expires next month.	One view of every gateway in the estate. A fix is made once and applied everywhere instead of forty separate visits.	<u>FleetOps</u> \$4,995. Worth it from roughly ten sites up.
An older Siemens or CTI 505 rack sitting behind a translator box with its own license and its own patching.	The translator box comes out, along with its license and its patching.	<u>TI 505 / CTI 2500 driver</u> \$695. No SparkBridge required.
Substation equipment speaking IEC 104, reached today through a protocol converter.	A direct connection from the gateway to the equipment, with the converter and its failure points removed.	<u>IEC 60870-5-104 driver</u> \$695. Reads only, no control path.
Utility equipment on DNP3, with another vendor's converter in the path.	The same fix as the other drivers: a direct connection, reads only, one less box to maintain.	<u>DNP3 driver</u> \$695. No SparkBridge required.

IF THIS IS YOUR SITUATION	WHAT CHANGES FOR THE BUSINESS	WHAT YOU BUY
A new dashboard or an analytics project is coming, and it must not slow down the plant.	A new consumer of the data adds no load at the source. Cost tracks what the plant is doing, not how many people are watching.	<u>SparkBridge Host</u> \$1,495, or <u>Passage</u> \$1,995 for tools that already connect over industry standards.

All prices are US dollars, list, per gateway, bought once and kept. Not a subscription. Support is 20% per year, optional. Architecture Partners take 20% off list with deal registration, Founding Partners 40% on their first production estate ([partner program](#)), and volume discounts apply by site count. Development and testing is free, no time limit.

WIDE AREA

REMOTE SITES, EXPENSIVE LINKS

Cellular, satellite or radio links, where you pay for the data and the connection drops.

The problem

POLLING WASTES THE CONNECTION

Polling spends your data allowance asking questions whose answer is usually "nothing changed." An outage leaves a gap in the history that no later poll can fill. Nobody can name the tag that is actually spending the money. In a real three day capture, one vibration tag with no change threshold set was taking 50.7% of a site's monthly budget, at 47 times the next largest consumer.

What changes

SEND CHANGES, STORE DURING OUTAGES

Normal traffic tracks what the plant is doing. If the link drops, the site  saves readings to disk with their original timestamps and sends them when it reconnects. The history shows

the real curve, not a flat line and a jump. The budget becomes a measured list you can act on. Readings you mark critical are protected in the sending path itself, so no budget rule can quietly degrade them.

Products in play: SparkBridge Edge, [SparkLink](#) for the data budget, and [SparkVault](#) if the history has to survive the outage as well as the link.

CONSOLIDATION

MANY SITES, ONE SERVER

A real example: one central server carrying 40 sites, sitting at 50 to 75% CPU, using 14 GB of memory, unable to ride out a network outage, getting worse every time someone added a dashboard.

280k to 300k metrics. That estate's consolidated published metrics, sized from real gateway backups.

500k in under 4 GiB. The measured single-host capacity, with per-metric cost flat to a million. The fleet fits with margin on every dimension.

Cost does not grow with consumers. Adding a dashboard, a historian or an ML pipeline adds a subscriber, not load at the source.

The estate stays visible. Forty gateways is forty version numbers, forty certificate expiries and forty backup schedules. On a 40-site rig, one authorized certificate rotation reached every site in 937 ms, and the same instruction captured and replayed was refused by all forty.

Products in play: SparkBridge Host and SparkBridge Edge, with [FleetOps](#) once the site count is too large to track by hand.

UNS

ONE SOURCE OF PLANT DATA

This just means every system reads the same up-to-date picture of the plant from one place. You get it by publishing properly, not by buying something else.

The namespace populates itself. Each site describes itself at birth, so a new consumer subscribes and discovers the estate rather than being configured for it.

Readable, not just fast. The same values are also published on a plain, readable path, for people and tools that were never going to read a machine format.

One number, calculated once. Efficiency, throughput and cost per unit are computed in one place and published back as plant data, each value carrying the time of its oldest input and going bad when any input does. That is what makes a reported figure defensible.

Everything you already own can read it. The same live values are served to the historian, SCADA package or analytics tool you are not going to replace, with source timestamps intact.

Products in play: [Passage](#) for the systems you already own, [SparkCalc](#) for the derived numbers, [SparkVault](#) for the history behind them, and [SparkInject](#) when the warehouse is the destination.

OT IT

PLANT TO IT, SAFELY

The security question that matters here is what a compromised site can do to the rest of the estate.

Inbound firewall rules	The site connects outbound only. No inbound port into the plant network is required for data to flow.
A compromised site publishing as another	Each site has its own identity, bound to its own name. An unlisted identity is denied outright.
A compromised site issuing commands	Site identities cannot send commands at all. Command injection is structurally unavailable, not just discouraged.
A compromised site forging enterprise data	Every identity is authorized per data path and denied by default, whether the deployment is on our system or a third party's.
Credentials on the box	Secrets live in a permission-restricted file, not in a place any local user on the machine can read.
Rules typed by hand	Permissions are generated from stated intent, one line per action, and the change is shown as a difference before it is applied. A change that would lock you out of your own system is refused.
Proving any of this to an auditor	A scored assessment with ranked findings, the evidence behind each one and the fix. The first run against our own estate found four genuine defects, one of them critical.

Products in play: [SparkID](#) for the permissions, [Sentinel](#) for the assessment and the evidence.

WHAT IT COSTS

WHAT A WHOLE SOLUTION LOOKS LIKE

Three worked examples at list price. Every figure below comes from the price list. Nothing here is per tag, per device or per connected client.

One remote site on a metered link. A single wellhead or pump station on cellular, where the link drops, the allowance costs money, and the history has to survive both.

That is SparkBridge Edge, \$995, standalone; SparkLink is included. History is kept where the data lands: SparkVault runs on the Host gateway, so if this site is also your only server, it is that server that takes SparkVault at \$3,995.

Nothing central is required. One site is a complete deployment. Development use is free while you decide.

ONE SITE, AT LIST

SPARKBRIDGE EDGE	\$995
SPARKLINK	Free, included
AT THE SITE	\$995, standalone
SPARKVAULT, ON THE CENTRAL SERVER	\$3,995

A 40-site estate. Thirty-nine sites publishing to one Host gateway that hosts the estate and serves everything downstream of it.

At list that is $39 \times \$995 + 1 \times \$1,495$, which is \$40,300, once, before any volume discount. There is no per-tag, per-device or per-connected-client charge. The number does not move when the tag count does or when the third dashboard arrives.

Support is 20% per year, optional. Volume discounts apply by site count and are quoted. Architecture Partners take 20% with deal registration; the first five Founding Partners take 40% on their first production estate. [Partner program](#).

FORTY SITES, AT LIST

39 × SPARKBRIDGE EDGE	\$38,805
1 × SPARKBRIDGE HOST	\$1,495
TOTAL	\$40,300, once

BEFORE	Volume discount by site count
--------	-------------------------------

PER TAG OR PER CLIENT	Nothing
-----------------------	---------

A utility adding two substations on IEC 104. The equipment is already there and already speaks the protocol. What is in the way is a converter per site, with its own license, its own patching and its own failure mode.

The driver has its own license and its own price. It does not require SparkBridge, so this is the whole cost.

The same figure applies to a DNP3 site, or to an older Siemens or CTI 505 rack on the TI 505 driver.

TWO SUBSTATIONS, AT LIST

IEC 60870-5-104 DRIVER, SITE ONE	\$695
-------------------------------------	-------

IEC 60870-5-104 DRIVER, SITE TWO	\$695
-------------------------------------	-------

SPARKBRIDGE REQUIRED	No
----------------------	----

TOTAL	\$1,390, once
-------	---------------

CONTROL PATH	None. The drivers read only
--------------	-----------------------------

START WITH ONE SITE

Each of these shapes is drawn out on the [architecture page](#), including the 40-site and 200-plant layouts.

Try it on one site. Development use is free, no time limit.
